

Dynamic and Temporal Answer Set Programming on Linear Finite Traces

Pedro Cabalar¹ and Torsten Schaub²

The logical foundations of Answer Set Programming (ASP; [18]) rest upon the logic of Here-and-There (HT; [16]), or more precisely its equilibrium models [19] that correspond to stable models semantics [13]. For defining extensions to ASP from firm logical principles, it has thus become good practise to first elaborate upon them in the setting of HT in order to afterwards consider the respective language fragments that are well suited in the context of logic programming.

This avenue was also followed in [9], which gave rise to the temporal extension of HT called *Temporal Here-and-There* and its non-monotonic counterpart *Temporal Equilibrium Logic* (for short THT and TEL [1]). More precisely, TEL builds upon an extension of the logic of HT with Linear Temporal Logic (LTL; [20]). This results in an expressive non-monotonic modal logic, which extends traditional temporal logic programming approaches [7] to the general syntax of LTL and possesses a computational complexity beyond LTL [4]. As in LTL, a model in TEL is an *infinite* sequence of states, called a *trace*. However, this rules out computation by ASP technology (and necessitates model checking) and is unnatural for applications like planning, where plans amount to finite prefixes of one or more traces (cf. [2, 10]).

Unlike this, we recently proposed in [8] an alternative combination of the logics of HT and LTL whose semantics rests upon *finite* traces. On the one hand, this amounts to a restriction of THT and TEL to finite traces. On the other hand, this is similar to the restriction of LTL to LTL_f advocated by [10]; see also [2]. Our new approach, dubbed TEL_f , has the following advantages. First, it is readily implementable via ASP technology. Second, it can be reduced to a normal form which is close to logic programs and much simpler than the one obtained for TEL. Finally, its temporal models are finite and offer a one-to-one correspondence to plans. Interestingly, TEL_f also sheds light on concepts and methodology used in incremental ASP solving when understanding incremental parameters as time points.

Another distinctive feature of TEL_f is the inclusion of future as well as past temporal operators. We associate this with the following benefits. When using the causal reading of program rules, it is generally more natural to draw upon the past in rule bodies and to refer to the future in rule heads. A similar argument was put forward by [11] in his proposal of “declarative past and imperative future.” This format also yields a simpler normal form and lends itself to a systematic modeling methodology which favors the definition of states in terms of the past rather than mixing in future operators. For instance, in reasoning about actions, the idea is to derive action effects for the current state and check their preconditions in the previous one, rather than to represent this as a transition from the current to the next state. This methodology aligns state constraints, effect axioms, etc. to capture the present state. As well, past operators are much easier

handled computationally than their future counterparts when it comes to incremental reasoning, since they refer to already computed knowledge.

TEL_f is implemented in the `telingo` system, extending the ASP system `clingo` to compute the temporal stable models of (non-ground) temporal logic programs. To this end, it extends the full-fledged input language of `clingo` with temporal operators and computes temporal models incrementally by multi-shot solving [12] using a modular translation into ASP. `telingo` is freely available at [github](https://github.com/potassco/telingo)³. The interested reader might have a good time playing with the examples given in the `examples` folder at the same site.

Similar to the extension of LTL_f to its (linear) dynamic logic counterpart LDL_f [10], we just introduced in [3] a dynamic extension of HT that draws up upon this linear version of dynamic logic. We refer to the resulting logic as (*Linear*) *Dynamic logic of Here-and-There* (DHT for short). As usual, the equilibrium models of DHT are used to define temporal stable models and induce the non-monotonic counterpart of DHT, referred to as (*Linear*) *Dynamic Equilibrium Logic* (DEL). In doing so, we actually parallel earlier work extending HT with LTL, ultimately leading to THT and TEL.

In fact, we show that THT (and its equilibrium counterpart TEL) can be embedded into our new logic DHT (and DEL, respectively) — just as LTL can be put in LDL. Moreover, we prove that the satisfiability problem in DEL is EXPSpace-complete; it thus coincides with that of TEL but goes beyond that of LDL and LTL, both being PSPACE-complete. In fact, the membership part of this result is obtained by means of an automata-based method for computing DEL models. Finally, we show that the monotonic base logic of DEL, namely DHT, allows us to decide strong equivalence in DEL; this reinforces the adequacy of the relation between both logics.

These recent results open several interesting topics for future study. First, the version of DEL for finite traces, DEL_f , seems a natural step to follow, similar to the relation of LDL and LDL_f . We plan to propose and analyse this variation in an immediate future. As a second open topic, it would be interesting to adapt existing model checking techniques (based on automata construction) for temporal logics to solve the problem of existence of temporal stable models. This was done for infinite traces in [6, 5], but no similar method has been implemented for finite traces on TEL_f or DEL_f yet. The importance of having an efficient implementation of such a method is that it would allow deciding non-existence of a plan in a given planning problem, something not possible by current incremental solving techniques. Another interesting topic is the optimization of grounding in temporal ASP specifications as those handled by `telingo`. The current grounding of `telingo` is inherited from incremental solving in `clingo` and does not exploit the semantics of temporal expressions that are available now in the input language. Finally, we envisage to extend the `telingo` system with features of DEL in order to obtain a powerful system for representing and reasoning about dynamic domains, not only providing an effective implementation of TEL and DEL but, furthermore, a platform for action and control languages, like $\mathcal{A}, \mathcal{B}, \mathcal{C}$ [14, 15] or GOLOG [17].
